Active Portfolio Management and Investment Policy

Source: Bodie, Kane and Marcus, Investments, 12 ed., McGraw-Hill, 2021

Overview

- Consider practical complexities in the process of constructing optimal portfolios
- Treynor-Black model
 - Show how to handle limited precision in the forecasts of alpha values and the extreme portfolio positions often prescribed by the model
- Black-Litterman model
 - Allows flexible views about the expected returns of major asset classes to improve asset allocation
- Investment Policy

Construction and Properties of the Optimal Risky Portfolio 1

• Table 27.1 Construction and properties of the optimal risky portfolio

1.	Initial position of security <i>i</i> in the active portfolio	$W_i^0 = \frac{\alpha_i}{\sigma^2(e_i)}$
2.	Scaled initial positions	$W_{i} = \frac{w_{i}^{0}}{\sum_{i=1}^{n} \frac{\alpha_{i}}{\sigma^{2}\left(e_{i}\right)}}$
3.	Alpha of the active portfolio	$\alpha_A = \sum_{i=1}^n W_i \alpha_i$
4.	Residual variance of the active portfolio	$\sigma^2(e_A) = \sum_{i=1}^n W_i^2 \sigma^2(e_i)$
5.	Initial position in the active portfolio	$W_A^0 = \frac{\frac{\alpha_A}{\sigma^2(e_A)}}{\frac{E(R_M)}{\sigma_M^2}}$

Construction and Properties of the Optimal Risky Portfolio 2

• Table 27.1 Construction and properties of the optimal risky portfolio

6.	Beta of the active portfolio	$\beta_A = \sum_{i=1}^n W_i \beta_i$
7.	Adjusted (for beta) position in the active portfolio	$W_A^* = \frac{W_A^0}{1 + (1 - \beta_A) W_A^0}$
8.	Final weights in passive portfolio and in security <i>i</i>	$W_M^* = 1 - W_A^*; \qquad W_i^* = W_A^* W_i$
9.	The beta of the optimal risky portfolio and its risk premium	$\beta_{P} = W_{M}^{*} + W_{A}^{*}\beta_{A} = 1 - W_{A}^{*}(1 - \beta_{A})$ $E(R_{P}) = \beta_{P}E(R_{M}) + W_{A}^{*}\alpha_{A}$
10.	The variance of the optimal risky portfolio	$\sigma_P^2 = \beta_P^2 \sigma_M^2 + \left[W_A^* \sigma(e_A) \right]^2$
11.	Sharpe ratio of the risky portfolio	$S_P^2 = S_M^2 + \sum_{i=1}^n \left(\frac{\alpha_i}{\sigma(e_i)} \right)^2$

The Optimal Risky Portfolio 2

• Table 27.2 The optimal risky portfolio with the analysts' new forecasts of alpha

			Overall Portfolio						
Beta	1	0.9538	0.7323	0.4691	0.6892	1.4069	1.6129	1.3624	0.2532
Risk premium	0.06	0.2590	1.2132	0.2692	0.2492	0.2304	0.3574	0.2077	0.0761
SD	0.1358	0.1568	0.5224	0.3817	0.2901	0.1935	0.2611	0.1822	0.1988
Sharpe ratio	0.44	1.65	2.3223						
<i>M</i> -square	0	0.1642	0.2553						
Benchmark risk			0.5146						

- The Sharpe ratio increases from .44 to 2.32, a huge risk-adjusted return advantage
- M-square of 25.53%

Results: Problems

- Potential major problem with Treynor-Black model
 - The optimal portfolio now calls for extreme long/short positions that may not be feasible for a real-world portfolio manager
 - Most of this risk is nonsystematic because the beta of the active portfolio, at .95, is less than 1.0, and the beta of the overall risky portfolio is even lower, at only .73, because of the short position in the passive portfolio
- A solution: Restrict extreme portfolio positions
 - This results in a lack of diversification

The Optimal Risky Portfolio, Constrained $(w_A \le 1)_1$

The Optimal Risky Portfolio, Constrained $(w_A \le 1)_2$

• **Table 27.3** The optimal risky portfolio with constraint on the active portfolio ($w_A \le 1$)

			Overall Portfolio						
Beta	1	0.9538	0.9538	0.0810	0.1190	0.2428	0.2784	0.2352	0.0437
Risk premium	0.06	0.2590	0.2590	0.2692	0.2492	0.2304	0.3574	0.2077	0.0761
SD	0.1358	0.1568	0.5224	0.3817	0.2901	0.1935	0.2611	0.1822	0.1988
Sharpe ratio	0.44	1.65	1.6515						
<i>M</i> -square	0	0.1642	0.1642						
Benchmark risk			0.0887						

- Volatility of the overall portfolio (0.53) is high
- The Sharpe ratio falls from 2.32 to 1.65
- M-square is now .1642

Tracking Error 1

- Most investment managers are judged on performance relative to a benchmark portfolio
- Such commitment raises the importance of tracking error

Tracking Error =
$$T_E = R_P - R_M$$

where
$$R_P = w_A^* \alpha_A + \left[1 - w_A^* \times (1 - \beta_A)\right] \times R_M + w_A^* e_A$$

$$T_E = w_A^* \alpha_A - w_A^* \times (1 - \beta_A) \times R_M + w_A^* e_A$$

$$Var(T_E) = \left[w_A^* (1 - \beta_A)\right]^2 Var(R_M) + Var(w_A^* e_A) = \left[w_A^* (1 - \beta_A)\right]^2 \sigma_M^2 + \left[w_A^* \sigma(e_A)\right]^2$$
Benchmark risk = $\sigma(T_E) = w_A^* \sqrt{(1 - \beta_A)^2 \sigma_M^2 + \left[\sigma(e_A)^2\right]}$

Tracking Error 2

Benchmark risk =
$$\sigma(T_E) = w_A^* \sqrt{(1-\beta_A)^2 \sigma_M^2 + \left[\sigma(e_A)^2\right]}$$

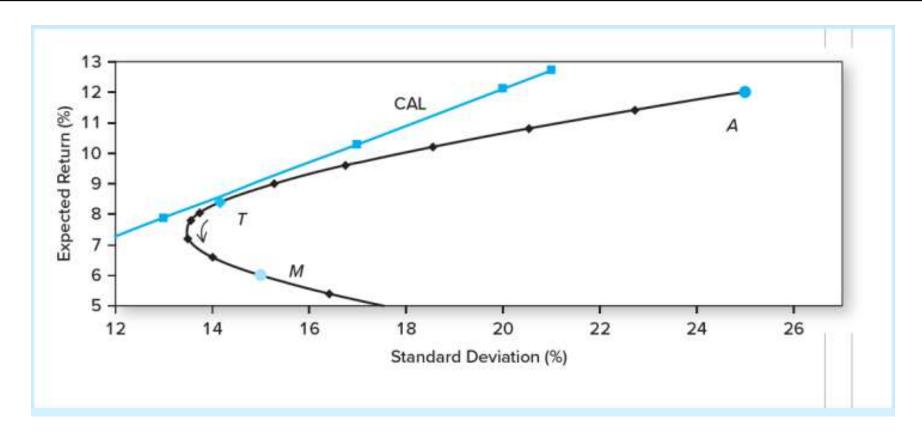

For a desired benhmark risk of $\sigma_0(T_E)$ and

$$\sigma_0\left(T_E; w_A^* = 1\right) = \sqrt{\left(1 - \beta_A\right)^2 \sigma_M^2 + \left[\sigma\left(e_A\right)^2\right]}$$

we can restrict the weight of the active portfolio to:

$$w_{A}(T_{E}) = \frac{\sigma_{0}(T_{E})}{\sigma(T_{E}; w_{A}^{*} = 1)}$$

Reduced Efficiency when Benchmark Risk is Lowered

- **Figure 27.1** Reduced efficiency when benchmark risk is lowered. Reducing tracking error risk results in a shift from the tangency portfolio, *T*, toward the benchmark portfolio, *M*.
- Benchmark risk is the standard deviation of the tracking error,
 T_E = R_P R_{M.} Control it by restricting W_A

The Optimal Risky Portfolio with the Analysts' New Forecasts

Sharpe ratio	0.44	1.65	1.0569						
<i>M</i> -square	0	0.1642	0.0835						
Benchmark risk			0.0385						

- The Sharpe ratio falls from 1.65 to 1.06
- M-square is now 8.35%

Adjusting Forecasts for the Precision of Alpha

- Key questions
 - How accurate is your forecast?
 - How should you adjust your position to take account of forecast imprecision?
- Treynor and Black
 - Examine forecasting record of previous forecasts issued by same forecaster to quantify the uncertainty about the forecast
 - Adjust forecasts to account for imprecision by using adjusted alpha

Organizational Chart for Portfolio Management

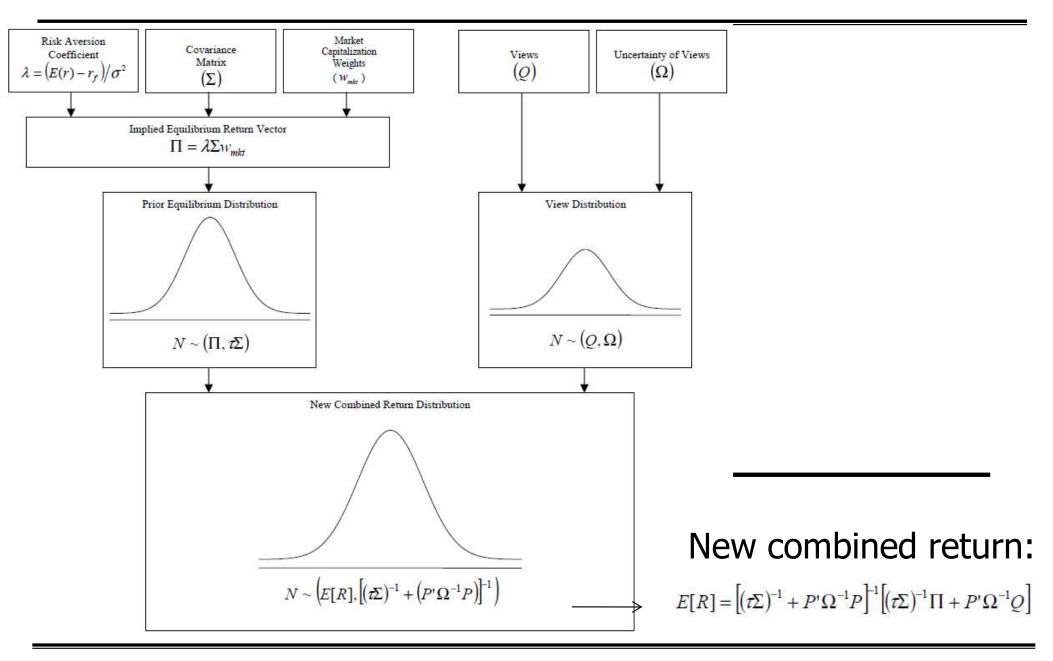

• Figure 27.3 Organizational chart for portfolio management

Black Litterman approach

Black and Litterman (1990) proposes a mean-variance portfolio optimization model that includes investor's expectations:

- Creates different views that represent investor's market expectations (investor's prior).
- Applies Bayes' rules to restrict sensitivity of optimal allocation function to model's inputs
- Market distribution (capitalization weighted market portfolio) is approximated to investor's prior
- Data hails from two sources: history and views
- Historical sample used to estimate covariance matrix and asset allocation to make baseline forecasts
- Views represent departure from baseline, establishing new alpha forecasts and optimal risky P

Black Litterman: combined return distribution

Source: Idzorek (2004)

Black Litterman approach

Starts with market equilibrium return & investors' views and obtains excess return in relation to the risk free rate:

$$E[R] = [(\tau \Sigma)^{-1} + P' \Omega^{-1} P]^{-1} [(\tau \Sigma)^{-1} \Pi + P' \Omega^{-1} Q]$$

P: investors' perspective vector

Omega: variance matrix of forecasts

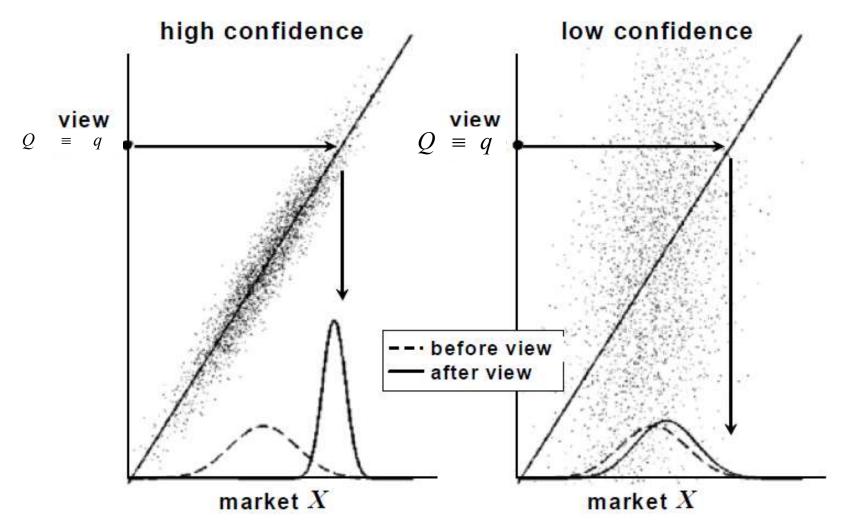

II: implied equilibrium return vector

Tau: confidence parameter

Q: investors' views expected return vector

Sigma: covariance matrix of returns

Black Litterman: market estimation

Scenario is different from market Scenario similar to market

Source: Meucci (2007)

Steps in the BL Model

- Estimate the covariance matrix from recent historical data
- Determine a baseline forecast
- 3. Integrate the manager's private views
- 4. Develop revised (posterior) expectations
- 5. Apply portfolio optimization

Sensitivity of Black-Litterman Portfolio to Confidence in Views 2

 Figure 27.4 Sensitivity of Black-Litterman portfolio performance to confidence level

T-B versus BL: Conclusions

- The BL and the Treynor-Black (TB) model are complements, not substitutes
- Once you reach the optimization stage, the models are identical
- BL can be viewed as generalization of TB
 - BL model allows you to adjust expected return from views about alpha values as in the TB model, but it also allows you to express views about relative performance that cannot be incorporated in the TB model

Black-Litterman Model

- Optimal portfolio weights and performance are highly sensitive to the degree of confidence in the views
- The validity of the BL model rests largely upon the way in which the confidence about views is developed

Treynor-Black Model

- TB model is not applied in the field because it results in "wild" portfolio weights
- The extreme weights are a consequence of failing to adjust alpha values to reflect forecast precision

BL versus TB₂

Black-Litterman Model

- Use the BL model for asset allocation
- Views about relative performance are useful even when the degree of confidence is inaccurately estimated

Treynor-Black Model

 Use the TB model for the management of security analysis with proper adjustment of alpha forecasts

Concluding Remarks

- The gap between theory and practice has been narrowing in recent years
- The CFA Institute has worked to transfer investment theory to the asset management industry
- The TB and BL models are not yet widely used in industry
